

Collaboratively Patching Linked Data

A Patch Repository for Linked Datasets

Magnus Knuth, Johannes Hercher,
and Harald Sack

Hasso Plattner Institute, University of Potsdam

USEWOD Workshop @ WWW 2012

April 17, 2012 - Lyon, France

Outline

- Introduction
- Patch Request Ontology
- Architecture / Workflow
- Use Case
 - WhoKnows?
 - Patch Repository
- Outlook

Problem

- the Web of Data is noisy
- dataset not under employers control
- erroneous Data distributed to multiple local data stores
- missing error correction propagation mechanisms
 - for commits, for updates

no read-write-web

performance
stability
integration

- examples from DBpedia:

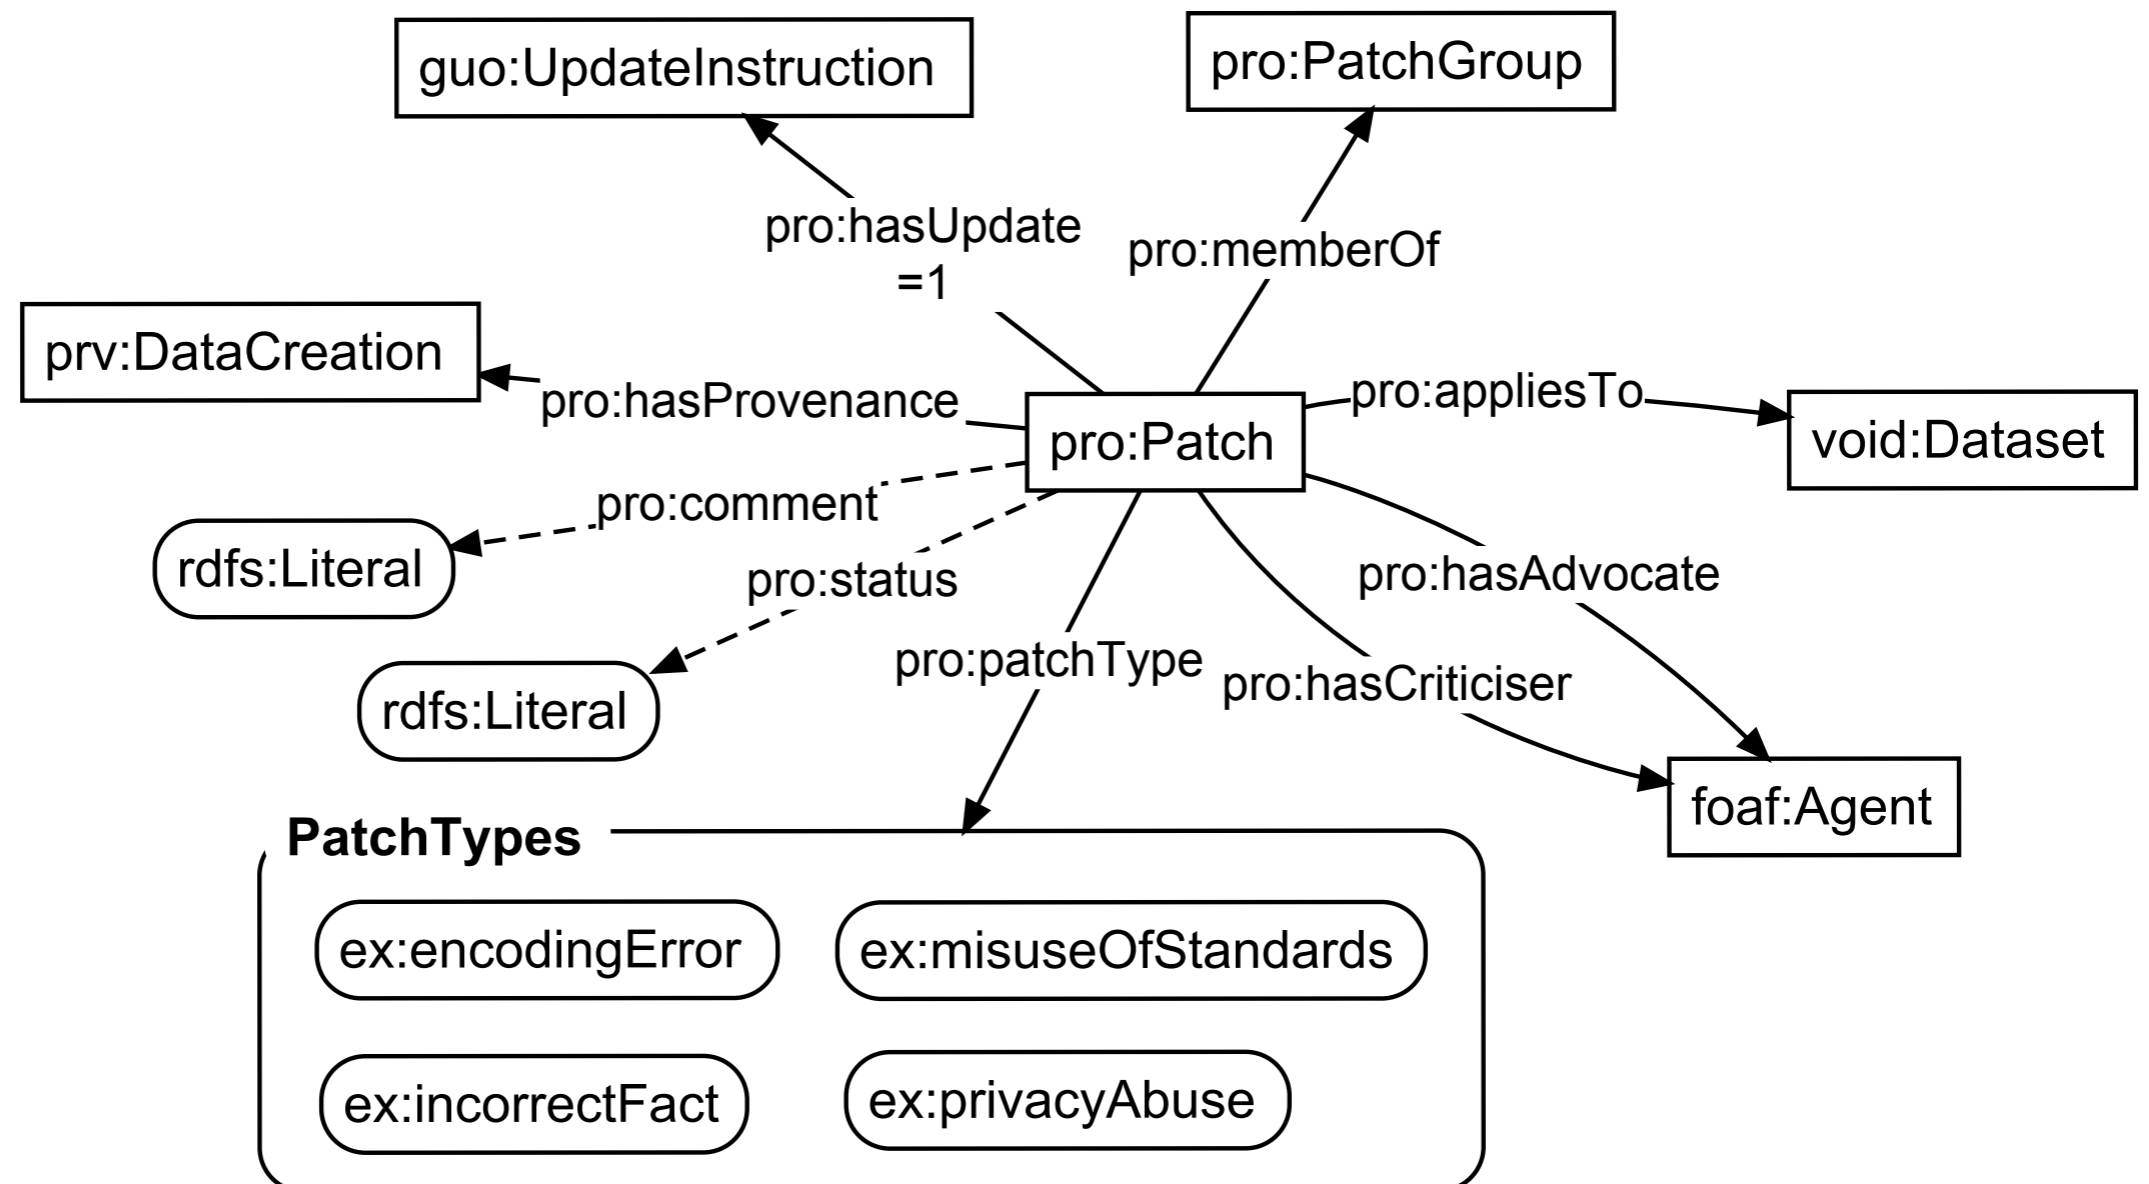

- `dbp:Ukraine dbo:anthem dbp:Transliteration,
dbp:Ukrainian_language .`
- `dbp:Fred_Records dbo:distributingCompany dbp:Japan,
dbp:United_States,
dbp:United_Kingdom .`
- `dbp:Rhode_Island dbo:language dbp:De_jure,
dbp:De_facto .`

Goals

- a solution that addresses Linked Data error corrections
- an ontology to describe error corrections for Linked Datasets
- a framework to collect Linked Data Patches in a collaborative way
 - explicitly involving data consumers
- a process to propagate Linked Data Patches over multiple local stores

Patch Request Ontology

- „a simple vocabulary to share data about erroneous triples“
 - <http://purl.org/hpi/patchr>

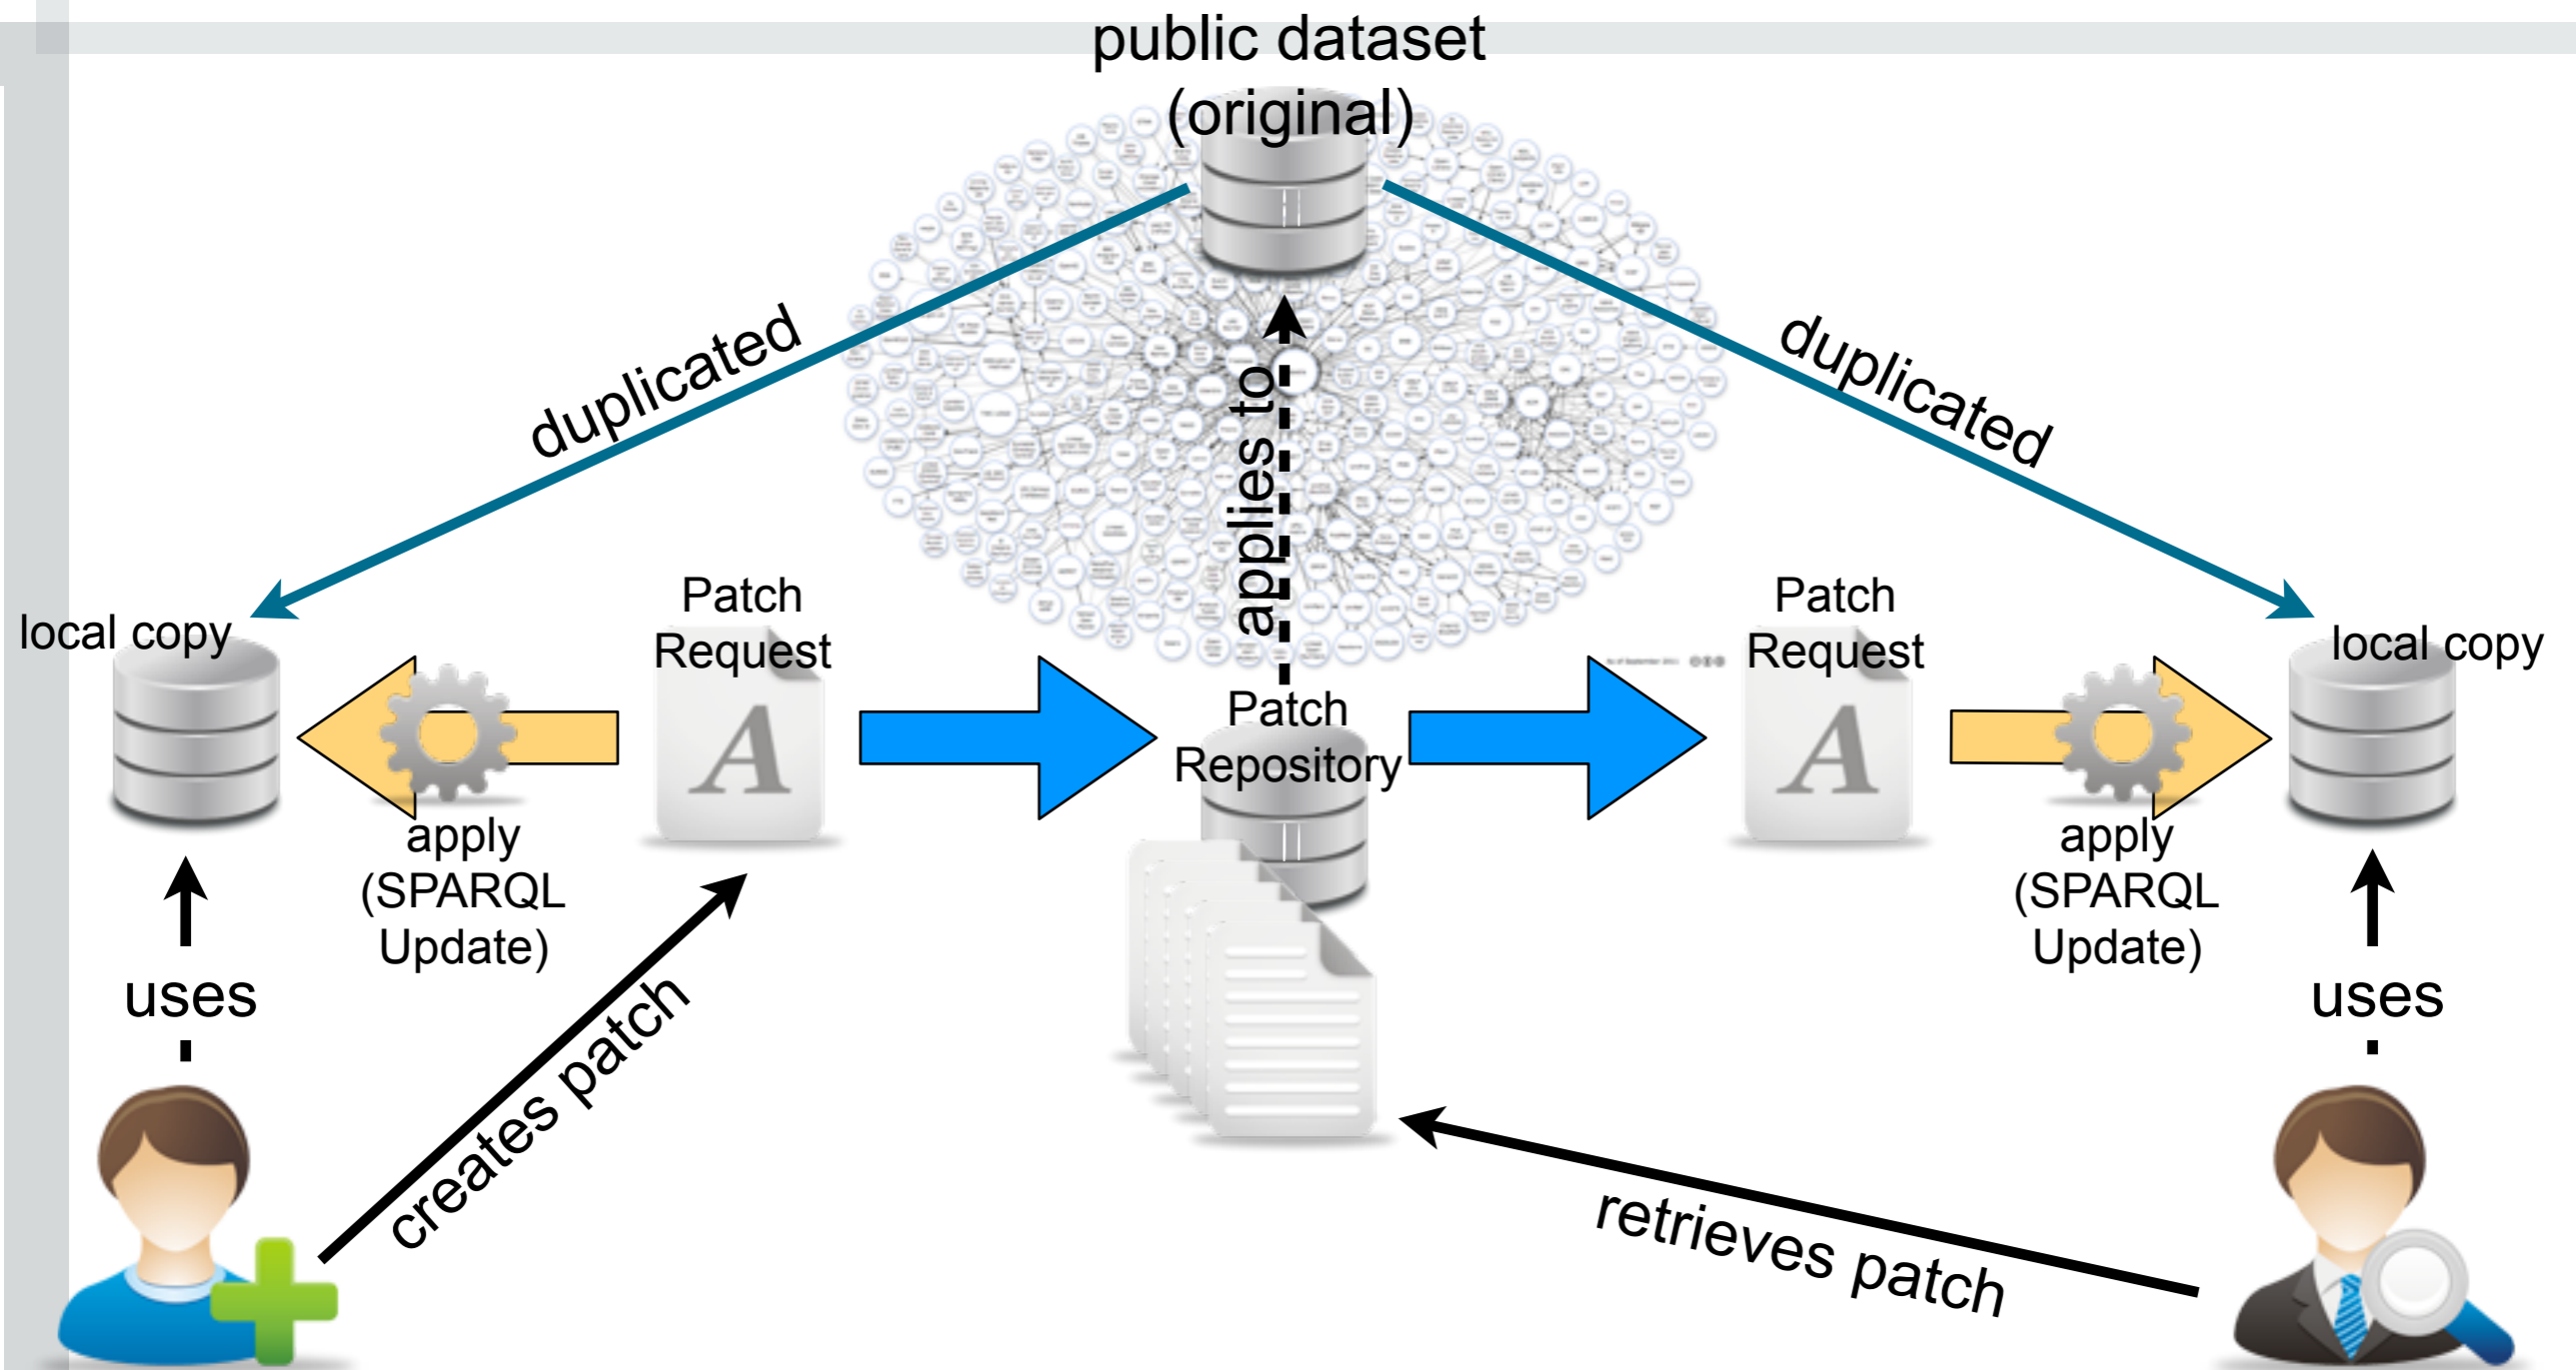

A Patch Request

```

repo:Patch_15 a pro:Patch ;
  pro:hasUpdate [
    a guo:UpdateInstruction ;
    guo:target_graph <http://dbpedia.org/> ;
    guo:target_subject dbp:Oregon ;
    guo:insert [
      dbo:language dbp:English_language ]
    ] ;
  pro:hasAdvocate repo:Player_25 ;
  pro:appliesTo <http://dbpedia.org/void.ttl#DBpedia> ;
  pro:status "active" ;
  pro:hasProvenance [
    a prv:DataCreation ;
    prv:performedBy repo:WhoKnows ;
    prv:involvedActor repo:Player_25 ;
    prv:performedAt "...^^xsd:dateTime ] .
  
```

Patch for exactly one triple

Architecture / Workflow

Workflow

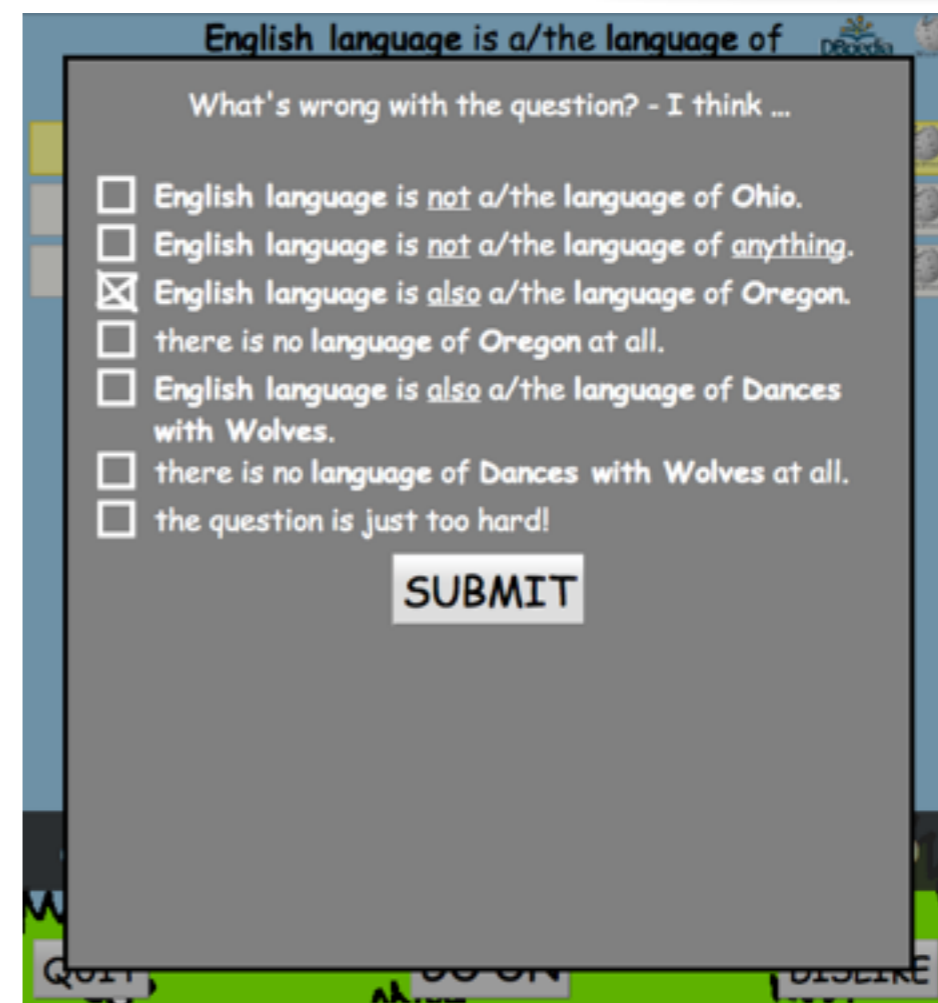

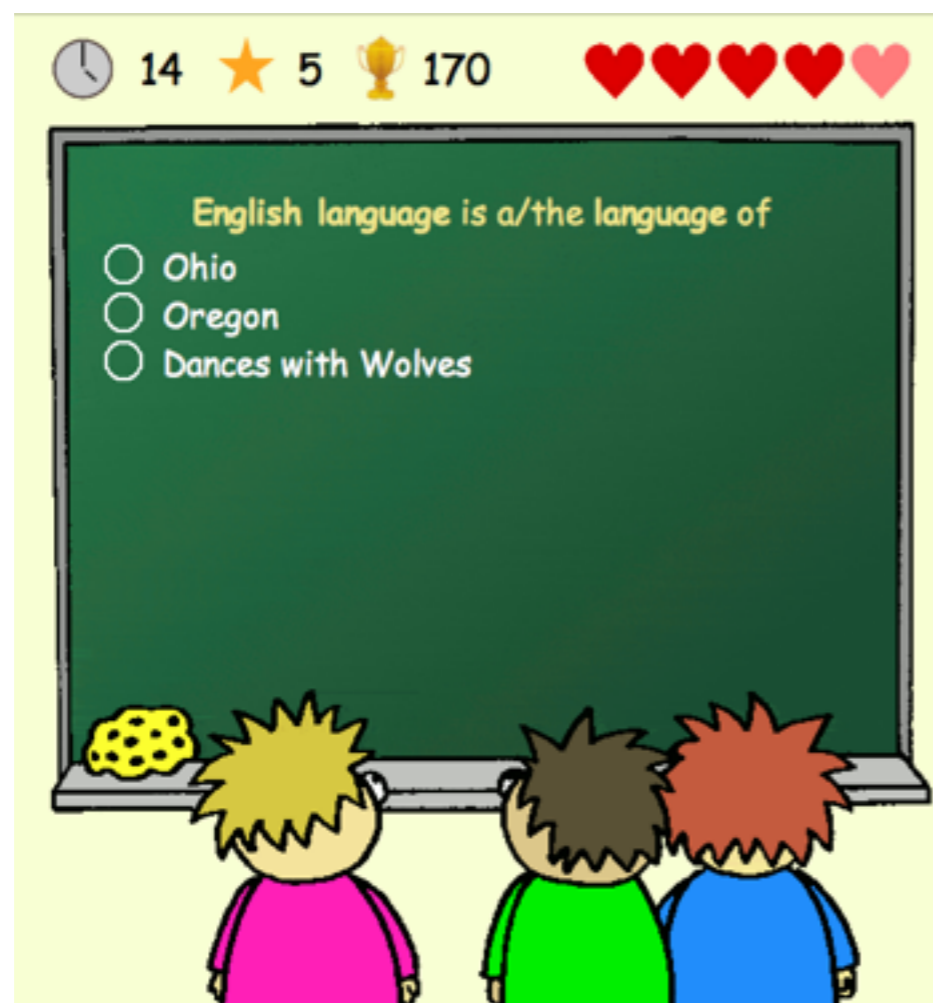

1. find an error
 - by human user or automatic algorithm
2. create a patch
3. commit to (central) repository
 - there should be one responsible repository for each dataset
 - if patch preexists: one more vote
4. other users / dataset providers retrieve patches from repository
 - via SPARQL query
 - customizable to individual requirements
5. apply updates to local dataset
 - easy transformation of patch request to SPARQL Update query

Use Case: *WhoKnows?*

- GWAP generates multiple choice questions from DBpedia facts
- player identifies wrong triples if the question (or desired answer) makes no sense
- generating patch from user vote

DEMO

[http://141.89.22543/
game.html](http://141.89.22543/game.html)

Patch Repository

- list most recent / most popular patches, individual filtering
- show patches for individual resources

DEMO

<http://141.89.225.43/patchr/browse.php>

Filtered Patch Requests

Result size: 7.

LOD Benefits

- collecting patches from crowdsourcing or algorithmic data curation systems
- providing patches for replicated Linked Datasets
 - improving data quality
 - measuring data quality
- sustainability (Use Case: DBpedia): fix errors at their source, i.e. Wikipedia

Outlook

- effective synchronization of patches
- further standardization

- dataset quality evaluation

- API to submit patches
 - validity checking
- advanced trust and access control mechanisms
 - rating patches (vote up/down)
 - provide feedback (comments)
 - reputation management
- pingback to inform dataset providers

Thanks for your attention!
