

# Word Alignment

IT Systems Engineering | Universität Potsdam

Dr. Mariana Neves  
(adapted from the original slides  
of Prof. Philipp Koehn)

November 14th, 2016

- Further discussion on word alignment, such as problems and quality measurement
- Present a method on word alignment based on the IBM models

Given a sentence pair, which words correspond to each other?

	michael	geht	davon	aus	,	dass	er	im	haus	bleibt
michael	■									
assumes		■	■	■						
that						■				
he							■			
will										■
stay										■
in								■		
the								■		
house									■	

- It does not need to be one-by-one.
- Words can have multiple or no alignment points.

	john	wohnt	hier	nicht
john	■			
does		?		?
not				■
live		■		
here			■	

Is the English word **does** aligned to the German **wohnt** (verb) or **nicht** (negation) or neither?

	john	biss	ins	grass
john	■			
kicked		■	■	■
the		■	■	■
bucket		■	■	■

How do the idioms **kicked the bucket** and **biss ins grass** match up?  
Outside this exceptional context, **bucket** is never a good translation for **grass**

# Word Alignment?

	john	biss	ins	grass
john	■			
kicked		■	■	■
the		■	■	■
bucket		■	■	■

The better solution here is a phrasal alignment!

- Sure alignments:
  - John to John
- Possible alignments:
  - kicked to biss
  - the to im
  - bucket to Grass

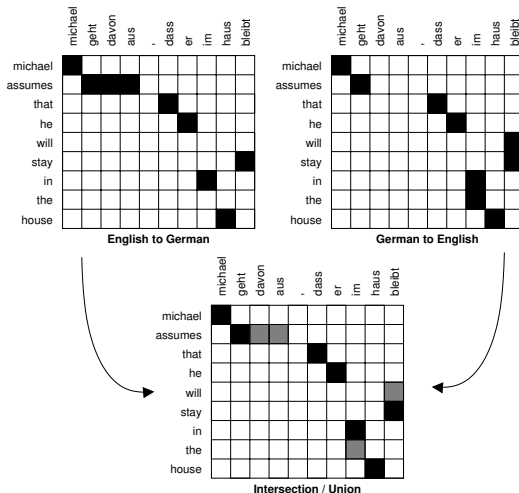

- Manually align corpus with *sure* ( $S$ ) and *possible* ( $P$ ) alignment points ( $S \subseteq P$ )
- Alignment Error Rate (AER): common metric for evaluation word alignments

$$\text{AER}(S, P; A) = 1 - \frac{|A \cap S| + |A \cap P|}{|A| + |S|}$$

- $\text{AER} = 0$ : alignment  $A$  matches all sure, any number of possible alignment points

- IBM Models create a **many-to-one** mapping
  - words are aligned using an alignment function
  - a function may return the same value for different input (one-to-many mapping)
  - a function cannot return multiple values for one input (no many-to-one mapping)
- Real word alignments have **many-to-many** mappings

# Symmetrizing Word Alignments

- Intersection of GIZA++ bidirectional alignments

- The **intersection** usually contains good alignment points (high precision), but not all of them.
- The **union** usually contains most of the desired align points (high recall), but also faulty points.
  
- We want to explore the space between the two extremes:
  - Take the all alignment points in the intersection (reliable).
  - Add some of the points from the union (neighboring candidates), incrementally.

**grow-diag-final**(e2f,f2e)

- 1: neighboring =  $\{(-1,0),(0,-1),(1,0),(0,1),(-1,-1),(-1,1),(1,-1),(1,1)\}$
- 2: alignment  $A = \text{intersect}(e2f,f2e)$ ; **grow-diag**(); **final**(e2f); **final**(f2e);

**grow-diag**()

- 1: **while** new points added **do**
- 2:     **for all** English word  $e \in [1\dots e_n]$ , foreign word  $f \in [1\dots f_n]$ ,  $(e, f) \in A$  **do**
- 3:         **for all** neighboring alignment points  $(e_{\text{new}}, f_{\text{new}})$  **do**
- 4:             **if**  $(e_{\text{new}}$  unaligned OR  $f_{\text{new}}$  unaligned) AND  $(e_{\text{new}}, f_{\text{new}}) \in \text{union}(e2f,f2e)$  **then**
- 5:                 add  $(e_{\text{new}}, f_{\text{new}})$  to  $A$
- 6:             **end if**
- 7:         **end for**
- 8:     **end for**
- 9: **end while**

**final**()

- 1: **for all** English word  $e_{\text{new}} \in [1\dots e_n]$ , foreign word  $f_{\text{new}} \in [1\dots f_n]$  **do**
- 2:     **if**  $(e_{\text{new}}$  unaligned OR  $f_{\text{new}}$  unaligned) AND  $(e_{\text{new}}, f_{\text{new}}) \in \text{union}(e2f,f2e)$  **then**
- 3:         add  $(e_{\text{new}}, f_{\text{new}})$  to  $A$
- 4:     **end if**
- 5: **end for**
